Title: Optical Combining System

Purpose: Particularly for combining three primary colored television images.

Advance over Prior Art: Perfect optical coincidence of overlapping images.

Description and Sketch: (See Sketch Attached)
Many systems of super-imposed projection have been proposed, particularly for use with color (Baird etc.). Most of them are unworkable because they are optically fundamentally unsound, or based on optical approximations which lose their validity at wide apertures and large angular fields of view.

The following system can be used either for the projection of standard films or slides or television primary pictures. In the latter case, certain simplifications are permissible, provided the teaching of this disclosure is followed.

In Figure 1 R1 G1 B1 are three similar, separate, possibly colored, rectangular, primary images, which may be film, slides or television primaries. LR1, LG1, LB1 are three similar projection lenses.

R2 (G2) B2 are secondary trapezoidal images of R1 G1 B1 produced by these lenses (G2 need not be trapezoidal).

In R1 G1 B1 the upper and lower (or left and right) parts of the primary images are equal: a = b.

In Rg (Gg) Bg the upper and lower parts of the secondary images are unequal.

In Rg a is smaller than b. (IN G_2 a = b).

In Bg a is greater than b.

Field lenses may be situated in or close to the planes Rg Gg Bg.

Wedge prisms may also be situated in planes Rg and Bg (in which case a plane parallel plate may be placed in plane Gg). These serve to bend the light in the required direction.

LRg LGg LBg are three further and similar projection lenses (not necessarily similar to LR1 LG1 LB1).

Witnessed and Understood: Mary Jean Gilman 7/16/45 Olga E. Yeaton 7/16/45 Date of Conception: Sept.-Nov., 1943 Signature of Inventor: Ernest Traub Date of Signature: 7/15/45 Department: 5857 Research Telephone Extension: 535 - 58 Lenses LRg LGg LBg serve to project the trapezoidal secondaries Rg Gg Bg onto the screen RGBT.

The three images R₁ G₁ B₁ now appear perfectly coincident and superimposed in rectangular form as the combined (tertiary) image RGB_T.

Reverting to Fig. 1, if lenses LR1 LG1 LB1 operate under a magnification condition of M1, then tan B1 = $\tan \alpha_1/M_1$.

Similarly, if lenses LRg LGg LBg operate under a magnification condition of Mg, then tan Bg = tan 42/Mg.

Now in television, unlike other fields, the elements R1 G1 B1 LR1 LG1 LB1 may be dispensed with. Predistorted primary or secondary images R2 (G2) B2 may be produced by means other than optical.

This type of predistortion may be carried out in a number of known ways. By means of front or rear scanned skew neck tubes whose locus of scanlies on a circle whose center is the bisector of the line joining the geometrical center of the trapezoid A and the convergence point B of the two sloping sides of the trapezoid. (Fig. 2)

Or the predistortion may be performed circuit-wise, or by predistorted magnetic fields (Fernseh, Fisher et al.)

The television images Rg Gg Bg may be separate tubes or in a common tube with three guns, or all scanned by one gun.

This principle may be applied to either the horizontal or vertical plane or a combination of both.
