P-3521 - R-7521

For information refer to Service Manual for P-342, R-742 series with the exception of the following differences:

TO CLEAN FACE OF PICTURE TUBE

- 1. Loosen the two set screws on the bottom of the lower ornamental strip.
- 2. Slide window panel out sideways.
- 3. Clean face of the picture tube and back of the window panel.
- 4. Replace window panel by sliding it in sideways and tighten the two set screws.
- 5. Clean face of the window panel.

WARNING: The safety window panel must always be replaced.

TELEVISION ANTENNA CONNECTIONS

An antenna that is satisfactory for strong local signals, in the absence of severe reflections, is built into the cabinet. This antenna also functions as the radiation shield, and must be connected to the ground terminal beneath the antenna terminal when used as the antenna.

If an external antenna is used, it should match the receiver's input impedance of 300 ohms.

DISCONNECT THE BUILT-IN ANTENNA WHEN USING THE EXTERNAL ANTENNA AND GROUND IT TO THE TERMINAL BENEATH THE ANTENNA TERMINALS.

HIGH VOLTAGE WARNING

Operation of the receiver chassis outside of the cabinet involves a shock hazard. The High Voltage supply, while of low equipment, operates up to 15,000 volts potential. Exercise all normal high Voltage precautions while working on this

BLOCK DIAGRAM

PICTURE TUBE WARNING

The picture tube envelope encloses a high vacuum and with the large surface area of glass involved, the stresses created are considerable. Any accidental blow or rough handling may cause the tube to implode with extreme violence. The picture tube should be handled only by qualified persons protected by heavy gloves and shatterproof goggles.

Always handle the picture tube by the front rim, never by the neck. Always set the picture tube face down on a piece of thick, soft paper or cloth.

SERVICE ADJUSTMENTS

The service adjustments normally will require occasional minor adjustments if any circuit work or tube replacement is required. A test pattern, generated locally in the shop, or obtained from a television station is recommended for best results. The operating and auxiliary controls on the front panel should be adjusted to give the best possible picture before making the following adjustments:

Centering the picture — Remove the back cover and adjust the two rings on the centering device until the picture is recentered. If any difficulty is encountered check that the neck of the picture tube is centered in the deflection yoke and adjust if necessary

Levelling the picture — Loosen the thumb screw on the deflection yoke assembly and rotate the yoke until picture is level. Push the yoke tight against the picture tube and tighten the thumb screw.

Size — Adjust the height and width controls so that the picture fills out the dimensions of the screen.

Linearity - Adjust the vertical linearity control for a symmetrical pattern.

Brightness — Readjust the ion trap for maximum brilliance and best focus. The brilliance control should be backed off to about % maximum brilliance when making this adjustment.

NOTE: The sequence of service controls adjustments outlined is suggested as a convenient method of approach. Variations of the procedure are permitted to obtain the final result, but always check the setting of the ion trap as the final

TO CLEAN PICTURE TUBE FACE OF THE 21" MODELS

- While pressing gently against the window panel, remove the four screws from the ornamental strip.
 Set aside the ornamental strip and lift out the window panel.
 Clean the face of the picture tube and the back of the window panel.

- Replace the window panel by pushing it into the slot at the top of the cabinet and then setting it on the bottom platform.
 Adjust the two plastic strips at the side of the glass to ensure a tight fit in the cabinet.
- 5. Replace the ornamental strip and clean the face of the window panel.

WARNING: The safety window must always be replaced.

TO REMOVE THE CHASSIS FROM THE CABINET

- 1. Disconnect the power supply cord.
- 2. Disconnect the built-in antenna leads and the external antenna.
- 3. Pull off all knobs.
- 4. Remove the back cover and swing it to the top of the cabinet.
- 5. Disconnect the speaker plug and on 21" console models only, pull the speaker lead below the chassis.
- 6. Remove the four chassis mounting bolts and slide the chassis out.

TO REMOVE THE PICTURE TUBE FROM THE CHASSIS

- 1. Disconnect the H.V. anode connector from the side of the picture tube and discharge it to the chassis.
- 2. Discharge the anode contact of the picture tube to the chassis.
- 3. Remove the picture tube socket.
- 4. Remove the ion trap.
- 5. Remove the screw holding the top strap to the side bracket.
- 6. Remove the two front clamping brackets by unscrewing from the side brackets.
- 7. Lift the front of the picture tube slightly and pull forward until the back is clear of the yoke assembly.

CAUTION: If the picture tube fails to slip out smoothly, investigate and remove the cause of the trouble. DO NOT USE FORCE.

INSTALLING AND ADJUSTING THE PICTURE TUBE

- 1. With the H.V. anode to the left, slip the neck of the picture tube through the deflection yoke assembly, seating the rim of the picture tube on the supporting strap. Then pull the support strap forward. The ground spring should be bent downwards from the support bracket so that it fits under the tube.
- 2. Screw the front clamping brackets in position. (See Note 1.)
- 3. Place the top strap round the rim of the tube and screw tightly to the side bracket.
- Make certain that the rubber collar of the yoke support rests firmly against the cone of the tube, and push the deflection
 yoke as far forward as possible.
- 5. Slip the ion trap over the neck of the picture tube, having the red dot underneath and the magnet on the left when looking at the rear of the chassis.
- 6. Connect the H.V. anode connector, the picture tube socket and the focus link on the base of the C.R.T.
- 7. Turn on the receiver and allow a few minutes to warm up.
- 8. Advance the brilliance control and adjust the ion trap for maximum brilliance. Back off the brilliance control below the defocusing point as the maximum brilliance is approached. The ion trap must be rotated about the axis of the picture tube as well as shifted along the neck, in order to obtain the correct setting.
- 9. Connect the antenna and tune in a test pattern.
- 10. Adjust the front controls to give the best possible picture.
- NOTE 1. To mount the front support strap correctly, the hole in the strap must be screwed in to the corresponding hole in the side bracket. It is not necessary for the same hole to be used at both sides. The center holes will normally provide the right height for the picture tube.
- NOTE 2. It is desirable that the position of the rear support bracket should not be altered. However, when fitting a replacement tube, it may be necessary to mount the support at a very slight angle in order to have the neck of the picture tube centered in the yoke and the face of the picture tube straight. The angle of the bracket may be altered by varying the position of the front and rear mounting screws in the three chassis mounting holes. If necessary, the rear support bracket may be screwed in position after the tube has been mounted. The measurements listed below should be used as a guide if any difficulty is experienced.

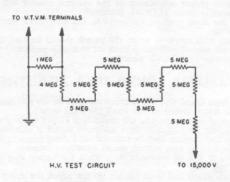

Model	Face of Tube to Face of Chassis	Bottom of Tube to Top of Chassis	Center of neck to Bottom of Chassis
A11 21"	1-3/16"	1-7/32"	13-5/16"
P342, R742	7/8"	5/8"	11-5/16"
P344, R744	1"	5/8"	113/4"

In all cases, the distance from the face of the chassis to the face of the knob panel should be 1¼" when the picture tube fits the mask.

HIGH VOLTAGE MEASUREMENT

DO NOT USE HAND-HELD FLEXIBLE TEST LEADS WHEN MAKING THE FOLLOWING MEASUREMENTS. KEEP THE HANDS CLEAR OF THE CIRCUIT DURING MEASUREMENT. A 12 TO 15 K.V. POTENTIAL EXISTS IN THIS CIRCUIT. EXERCISE ALL NORMAL HIGH VOLTAGE PRECAUTIONS.

To measure the H.V. Anode potential, set the CONTRAST and BRILLIANCE controls at minimum. With the controls in this position, the resistance of the test circuit will simulate the load presented to the H.V. power supply of the picture tube. Connect a test circuit as shown. Make the resistor string self-supporting and allow adequate clearance between the resistors and chassis parts to prevent high-voltage breakdown. A meter scale of 0 to 500 Volts, 20,000 ohms per volt sensitivity or better, should be used. Observe the reading on the meter scale and multiply this reading by 50 to obtain the voltage across the circuit. As an example, if the V.T.V.M. reads 260 volts, the potential is 260 x 50 or 13,000 volts.

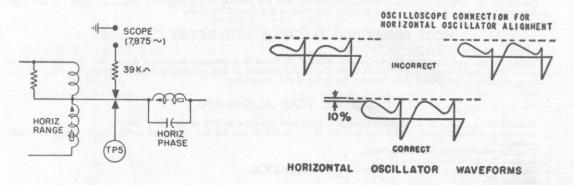

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to restore synchronization, the Horizontal Range adjustment should be reset.

- 1. Tune in a weak signal. (If a weak signal is not available attenuate the signal to approximately 100 uv at the input.)
- 2. Turn the Horizontal Hold control to extreme clockwise position.
- Adjust the Horizontal Range adjustment (L162) until a large vertical bar appears at the extreme left side of the picture tube. Then turn the Horizontal Range adjustment until the vertical bar just barely disappears to the left of the tube.
- Check the action of the Horizontal Hold control on all active channels. Repeat the above instructions if necessary to maintain stable synchronization.

NOTE: If the above procedure fails to restore stable synchronization, a waveform check may be made with the aid of an oscilloscope as follows:

5. Connect the oscilloscope as shown in the oscilloscope diagram. Adjust the phase adjustment (L163) until the saw tooth peak is equal to or slightly higher (not more than 10%) than the sine wave while maintaining the picture in synchronization with the Horizontal Range adjustment.

NOTE: This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is much lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious.

On the other hand, if the broad peak of the wave is higher than the sharp peak, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

- 6. Remove the oscilloscope and repeat steps Nos. 1, 2 and 3.
- 7. Check the action of the Horizontal Hold control and repeat the above steps as required to provide positive sychronization on all channels.

CIRCUIT FEATURES

RANGE FINDER SWITCH: This receiver is equipped with a four position switch which enables the receiver to operate over the full range of signal strengths. The correct setting of the switch can be determined by watching the synchronizing action of the receiver. The second position of the switch from full counterclockwise (adjacent to the LOCAL position) will be correct for most locations.

When a signal is so strong that proper adjustment of the contrast control will not remove bends in the picture, the switch should be turned fully counterclockwise (LOCAL position).

Similarly, if the switch is in the third position (adjacent to the DISTANT position) and the picture bends, it should be turned back to the second position.

When a signal is fair or normal with excessive noise, the switch should be turned to the third position. If a signal is so weak that adjustment of the contrast control will not correct an unsteady picture or possibly lose synchronization, then the switch should be turned fully clockwise (DISTANT position).

VARIABLE SOUND TRAP ADJUSTMENTS

In some extreme cases, it has been found that the nominal value of 32 db (40 times) rejection of the sound carrier in the I.F. amplifier may be too great (in fringe areas) or too small (in local areas).

To compensate for the extremes of signal strength, the sound trap (L31) spacing on the first I.F. coil may be varied. In fringe areas the spacing should be increased until adequate sound is obtained.

In very strong signal areas, the trap spacing may be reduced until sharp edges in the picture are free from a checkerboard effect. The sound should be checked to be sure enough sound sensitivity remains.

When the sound trap is moved it will be necessary to re-align the tuning slug associated with the trap coil. It is also advisable to re-align the first I.F. coil slug.

If the receiver is to receive both strong and weak signals, do not adjust the sound trap spacing.

POWER REQUIREMENTS

The total power consumption of this receiver has been reduced to approximately 150 watts. This results in a cool operating chassis and longer component life. The power economy is obtained by using the audio output tube as a stabilized voltage dropping impedance for the low voltage B + supply. Therefore, the audio power amplifier tube should not be removed from its socket while the set is operating.

CASCODE TUNER

The tuner embodies the latest developments in cascode circuits, and has a noise figure of only 5 to 9 db from the theoretical low limit. The R.F. Amplifier tube should not be replaced with any other type than that originally used, and the tuner should be re-aligned when a new tube is installed.

CENTERING DEVICE

The centering device consists of two magnetized rings which cancel each other when the tabs are together.

Separating the tabs, increases the effective magnetism and the amount of the centering action. Rotating the two rings together (at a given spacing of the tabs) provides centering in the desired direction.

A NOTE REGARDING ELECTROSTATIC FOCUS C.R. TUBES

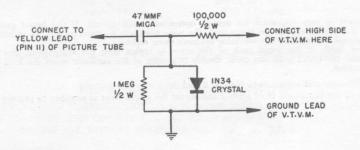

Arcing in the gun structure of electrostatic focus C.R. tubes is a common occurence during the first few hours of operation. This condition which is believed to be due to the presence of dust particles and minor impurities within the gun structure, subsides as the arcing itself removes the cause of the breakdown.

4.5 Mc. TRAP ALIGNMENT

Connect the 4.5 Mc. signal generator through a 5000 mmf capacitor to TP2 at the video detector.
 Connect a crystal detector circuit and a V.T.V.M. as shown in the 4.5 Mc. alignment test circuit to the picture tube

cathode.
Turn the contrast control fully clockwise.
Remove the 3rd video I.F. tube (V5).
Tune the 4.5 Mc. trap (L42) for minimum output on the V.T.V.M.

6. Replace V5.

SOUND ALIGNMENT TEST CIRCUIT

SOUND I.F. ALIGNMENT

Apply a 4.5 Mc. unmodulated signal to TP2 on the Video Detector. Connect a d-c V.T.V.M. to TP4, pin 2 of the Ratio Detector socket (V8). Set V.T.V.M. to —3 v scale.

Adjust the 4.5 Mc. Sound Take-off Coil (L131) for maximum V.T.V.M. reading. Do not exceed +3 volts.

Adjust the primary of the Ratio Detector (bottom) (L132-L133) for maximum V.T.V.M. reading.

Set the input for —3 volts on the V.T.V.M.

Connect the V.T.V.M. to TP5, the Ratio Detector Audio Output.

Adjust the Ratio Detector Secondary (top) (L134) for —1.5 V.

Apply approximately 30% amplitude modulation to the 4.5 Mc. signal and adjust L134 for minimum audio output.

Adjustments 6 and 7 should agree closely.

Repeat adjustments 3, 6 and 7 until there is no interaction of one adjustment on the other.

The 4.5 Mc. intercarrier I.F. can also be aligned by using the 4.5 Mc. F.M. signal developed by the station. Connect a V.T.V.M. to TP4 and using the Fine Tuning as signal input control to give as low a reading as possible on the V.T.V.M., adjust all 3 adjustments (Sound Take-off, Primary and Secondary of the Ratio Detector) for maximum reading.

VIDEO I.F. ALIGNMENT

- Turn Channel Selector to channel 3 or any signal free low channel.
 Place a tight fitting shield over V2, the 6U8 mixer tube, and connect the hot I.F. lead from a correctly terminated signal generator to the shield. (The shield must not be grounded). The generator case, however, must be grounded to the chassis as near as possible to the 6U8.
 Connect a decoupling network consisting of a 10,000 ohms resistor in series with a 1000 mmf condenser between TP3 and ground. Connect a d-c V.T.V.M. across the condenser which has one end grounded.
 Throughout the I.F. amplifier alignment use just enough signal input to give —2 V, d-c output at the video detector TP3.
 Set the signal generator to 44.1 Mc. and adjust L39-L40 for maximum output. If two peaks are found, use the one with the slug farthest out of the coil.

- Set the Signal Generator to 42.1 Mc. and adjust L39-L40 for maximum output. Set the Signal Generator to 42.8 Mc. and adjust L37-L38 for maximum output. Set the Signal Generator to 45.1 Mc. and adjust L34-L35 for maximum output. Set the Signal Generator to 47.25 Mc. and adjust L33, L36 for minimum output. Repeat steps 6, 7 and 8 until there is no interaction.

 Shunt a 180 mmf condenser from TP8 to ground.
- Set the Signal Generator to 42.8 Mc. and adjust L32, L7 for maximum output. Set the signal generator to 41.25 Mc. and adjust L31 for minimum output. Repeat steps 11 and 12 until there is no interaction.

- Remove shunt.
