SPECIFICATIONS

VOLTAGE RANGE.

FUSES.

This Model is fitted with a Heat Coil. Part No. 16705B. Yellow, 1.6 amp.

Nevertheless it is recommended that it should not be connected to a supply point fused to carry more than 5 amperes.

SPEECH OUTPUT.

Approximately 3 watts maximum.

WAVELENGTH RANGE.

Television, fixed tuned

{ 6.67 metres Vision.
 7.23 metres Sound.

Broadcast

{ 16.5— 52 metres Short Waves.
 200— 550 metres Medium Waves.
 750—2,000 metres Long Waves.

VALVES.

Marcon	i MSP4	H.F. Amplifier, television and broadcast (VI).
	X4IC	Frequency Changer, tele- vision and broadcast (V2).
•	KTZ41	I.F. Amplifier, television and broadcast (V3).
**	MDH4 (Met.)	Sound Detector and A.V.C. (V4).
24	KT4I	Sound output (V5).
••	KTZ4I	I.F. Amplifier, television only (V7).

Marconi KTZ41 I.F. Amplifier, vision only (V8). MS4B Vision Detector (V9). Pulse Diode (V16). D42 ,, KTZ63 Limiter (VIO). ,, Frame Oscillator (VII). KTZ63 11 Frame Output (V12). KT63 ** KTZ63 Line Oscillator (VI3). .. **KT63** Line Output (V14). ** UI7 Extra H.T. Rectifier (VI5). ** U52 H.T. Rectifier (V6).

Emiscope Tube type 3/1 (5 inch). 3/2 (7 inch).

Pilot Lamps 6 volts. Part No. 22704A.

LOUDSPEAKER.

No. 20277D.

A permanent magnet loudspeaker is employed on these models.

D.C. resistance of speech coil, 3.25 ohms. Impedance at 800 cycles, 3.75 ohms.

An extra loudspeaker may be connected to the sockets provided. The extra loudspeakers should be adjusted to a total impedance of approximately 5 ohms.

The internal loudspeaker may be silenced by removing the yellow plug from the third socket on the E.L.S. panel.

CONNECTING A PICK-UP.

A high resistance pick-up may be permanently connected to the sockets provided. The leads should be connected to the left-hand sockets and the lead screening to the right-hand socket.

CIRCUIT DESCRIPTION

Owing to the multiple functions of certain of the stages in this receiver the circuit diagram has been drawn to show these various functions. The central string of valves (VI, V2, V3, V7, V8, V9) are those which deal with the television signal from aerial to cathode ray tube. Branched off above are the valves (V4 and V5) used for sound (both television and broadcast), whilst the lower row (VI6, VI0, VI1, VI2, VI3, VI4) are valves employed in the separation and time base circuits and may be regarded as auxiliary to the main circuit. It will be noted that VI, V2 and V3 handle television (vision and sound) and broadcast sound signals; V7 is an I.F. amplifier for television (vision and sound) only, whilst V8 I.F. amplifier is for vision only, having in its cathode circuit a sound rejector (L27, C88, TC19).

H.F. AMPLIFIER.

A single tuned circuit for each of the wave bands

precedes the H.F. amplifier. In the case of television the tuning of L4 is sufficiently broad to accept both sound and vision signals. The A.V.C. which operates on this valve for broadcast reception is not used for television, and an adjustment of cathode bias is made by contacts D, 20, 23 of the wavechange switch to improve sensitivity on short waves and television. Tuned anode coupling is employed between this valve and the next stage.

FREQUENCY CHANGER.

The triode-hexode frequency changer has coupled coils (LII, LI4, LI2, LI5, LI3, LI6) for the production of oscillations on SW, MW and LW, giving an LF. frequency of 465 kc., whilst on television a stable centre-tapped circuit (LI7, CI8, TCI3) is employed and the resultant mean LF. frequencies are 8 Mc vision and 4.5 Mc sound.

I.F. AMPLIFIERS.

For broadcast two normal I.F. transformers (L9, L10 and L20, L21) are employed to couple the single I.F. amplifier stage (V3), but on television the system used is different. There are three I.F. amplifying stages the first two dealing with both sound and vision (bi-channel). The vision circuits (L18, L22, L24, L28) are "staggered" in frequency in order to endure adequate band width, whilst in series with the first three of these are circuits (L19, L23, L25) tuned for the sound signal. A coupling coil L26 coupled to the last sound circuit feeds the voltage to the diode of V4 for sound detection. The bias of V3 is adjustable by means of the potentiometer VR2 in the H.T.-feed. This is the "contrast" or sensitivity control.

SOUND DETECTOR AND OUTPUT STAGE.

The double diode-triode V4 is the second detector for sound, both producest and television. The sound detector diode is fed in the first case from the secondary of IFT2 and in the second case from the coupling coil mentioned above. The A.V.C. diode which is fed from the anode of V3 supplies A.V.C. voltage only in the case of broadcast sound. Resistance capacity (R23, C41) coupling is employed between V4 and the couple valve V5 which has a regardle feedback tone control circuit VR10, C84.

VISION DETECTOR AND SEPARATION.

The vision detector V9 is an anode bend detector fed from the tuned circuit L28. An H.F. choke (L29) in the anode circuit is followed by direct coupling (R65, C60) to the modulating electrode of the cathode ray tube which in this case is the cathode itself. The anode load for V9 is divided into two, R34 and R75. The action of the pulse diode V16 is virtually to short circuit R75 during the picture portion of the vision

signal. During the sync. pulses, however, a voltage is applied through C61 to the grid of the limiter V10. The valve limits the pulses to a certain value, and passes them on to trigger the frame and line oscillators from the anode and screen respectively via C66 and C68.

TIME BASES.

Hard valves operating on the "squegging" oscillator principle are used for both frame and line time bases. These circuits have the usual reaction transformers (T5, T6) and grid leak and condenser (R53, VR7, C71 and R46, VR6, C67). A feed-back condenser is fed from a tapping on the output transformer in the line circuit, and a waveform circuit (C79, R49, VR9) is connected across the secondary. In the frame circuit the output valve (V12) is resistance capacity coupled to the deflecting coils (L30, L31). The amplitude of the frame and line oscillations are controlled by varying the anode voltage by means of VR5 ("height") and VR4 (width).

THE C.R. TUBE.

The modulator (cathode) has already been described, and the other two electrodes (the tube is a triode) are the "grid" and the anode. A D.C. voltage derived from a potentiometer (VR5, VR3) across the H.T. feed is applied to the grid as bias, and variation of this voltage (by VR3) consequently varies the brightness. The second anode operates at approximately 2,500 volts fed from a half-wave rectifier (VI5) with the usual resistance capacity smoothing (R86, R59, C76, C77) and voltage stabilizing drain resistances (R60-R64). The focusing of the beam is done magnetically by means of a coil (L32) round the neck of the tube. This coil is enclosed in an Iron yoke, and adjustment of the current through the coil is done by VR8 (Focus control) and the pre-set adjustment of R85, R88.

H.F. TESTS AND ADJUSTMENTS

Do not attempt to make any adjustment to the circuits of this receiver unless you have adequate equipment as outlined below. All necessary oscillators, trimming tools, etc., essential for the correct adjustment of H.F. and I.F. circuits can be obtained from:—

E.M.I. Sales & Service Ltd.

INSTALLATION ADJUSTMENTS.

Further to the information given in the Service Sheet, an abridged instruction for installation (with recent modifications) is given below.

Aerial and Cable.

A properly designed aerial with a lead-in of the correct impedance (such as are obtainable from E.M.I. Sales & Service Ltd.) must be used to ensure good reception.

Pre-set Adjustments.

- I. Adjust focus by manual control, and if necessary pre-set adjustment. The focus adjustment screw should be inserted in one or other of the sockets at the back of the chassis until good sharp lines can be obtained with the Focus control.
- 2. Tune receiver oscillator trimmer (TCI3) as detailed on page 5.

IMPORTANT .- The first issue of the Service Sheet recommended the adjustment of L8 to obtain improved sound signal. This applies only to models with Serial Numbers prior to Model 904-H/2 1310, Model 905-H/2 3427, Model 706-H/2 282, Model 707-H/2 2512. On these models it may be noted that an improvement to both vision and sound signal can be obtained by fully unscrewing the plunger of L8. As the plunger is unscrewed (from the top of the chassis) a decrease and then an increase of signal should be observed, usually resulting in a final improvement.

To identify with certainty models which may have L8 adjusted remove the bottom cover and examine L8 coil former. If the former has no white spot, the plunger may be adjusted. If the former has a white spot this plunger must not be disturbed, irrespective of the advice in the first issue of the Service Sheet. For vision/sound ratio adjustment, see below.

3. Check that the correct amount of signal is reaching the receiver by noting the best position for the Contrast control. If too much signal is being received (contrast control near minimum), employ attenuation as detailed on page 12.

4. Check sound/vision ratio as detailed below.

5. In cases where it is difficult to make the picture "hold" (for instance, where field strength is weak) it may be possible to improve matters by adjusting the synch. control. Turn this control slightly clockwise, and again carefully adjust the Frame and Line Hold controls. The synch, control must not be turned so far clockwise that an intensification of the picture contrast is noticed.

Picture shape, size and position.

Pre-set controls at the back are provided for

"Height" and "Width" adjustment.
The "Form" adjustment need be touched only if the detail at the left-hand side of the picture has incorrect proportions.

The picture may be levelled and centred by moving

the scanning and focus coils respectively.

Re-fix the coils securely after making any adjustment.

Adjustment of Tuning and Sound/vision Ratio: On installation or after re-ganging it is essential to check the setting of TC13 on a television transmission

1. Turn Volume control fully up, and Contrast

control until sound is just heard.

2. Adjust TC13 for maximum sound. On some models TC13 is accessible from the top of the chassis, and on others from the bottom when the bottom cover is removed. Unclamp the rod and move up or down to trim.

WARNING .- In those models in which the trimmer is adjustable from the top of the chassis the rod is at HT+ voltage, and must therefore be adjusted with an insulated tool.

If sound is still low although there is now enough picture, unscrew TC16 to obtain a more satisfactory ratio.

If sound value is too high, causing modulation of the picture (bands across the picture, particularly on loud passages) TC16 should be screwed in.

GANGING.

The broadcast side of this receiver may be treated as an ordinary broadcast sound radio insofar as alignment of circuits is concerned. In the event of it being necessary to re-align the I.F. circuits, complete R.F. alignment must follow, but if only an R.F. circuit has been disturbed R.F. alignment in the order, SW, MW, LW, should be all that is required.

On television, if possible, even greater care must be exercised than on broadcast, otherwise picture quality will suffer. Generally speaking, low sensitivity or unsatisfactory picture/sound ratio is the result of mis-tuning in the R.F. circuits, whilst lack of definition in the picture is due to faulty I.F. alignment. As in broadcast, if the I.F. circuits are touched the R.F. circuits must be done.

The following are required for broadcast ganging :-

- (a) A modulated oscillator or signal generator with attenuator tuning from 16 to 1,900 metres (18.75 Mc, to 157 kc.).
- (b) An output meter or 0-2 A.C. voltmeter.
- (c) A trimming screwdriver with a minimum of metal in the blade, a tool for adjusting coil loops, and a tuning wand.

In addition for television ganging the oscillator must tune down to 6.67 metres (45 Mc.) and an 0-10 D.C. milliammeter, and an entirely non-metallic screwdriver are required.

BROADCAST RECEIVER.

The A.C. voltmeter should be connected across the extra loudspeaker sockets, or the anode of the sound output valve V5 and chassis if the E.M.I Service Output Meter is used. During all ganging operations the input to the receiver from the oscillator should be kept low, and progressively reduced as the circuits are brought into line so that the reading on the output meter does not exceed approximately 500 mW or 1.4 volts.

I.F. ALIGNMENT.

Set receiver to LW, tone control at maximum top, gang condenser to maximum, and volume control to maximum. The oscillator must be connected via a 0.1 mfd. condenser to the top cap of V2 (X41C), leaving grid connexion made.

1. Tune oscillator exactly to 465 kc. (645.2 metres).

2. Adjust TC6, TC7, TC14 and TC15 in that order for maximum output.

3. Check operation 2 in the same order.

NOTE.—If when the l.F. ganging has been done inerability is noted it may be necessary to move the made condensers in if it. Remove the can from this transformer and move CIO and CII up as close as possible to the coils they tune (i.e., L9 and L10 respectively). This should cure the instability.

SHORT WAVES.

Switch receiver to SW, set volume control to maximum, tone control to maximum top, and connect oscillator to aerial and earth sockets, via a suitable dummy aerial.

1. Set receiver gang condenser to minimum and tune oscillator to 16.7 metres (17.96 Mc.).

2. Adjust TC8 for maximum output.

3. Set oscillator and receiver (by scale) to 50 metres (6 Mc.) and adjust inductance loops L1, L5 and L11 for These loops will be found inside wimim autait the con formers, and may be adjusted by means of a strip of insulating material with a nick in it by bending the loop either towards or away from the chassis. The cans may be removed to identify the loops, but they must be in place when the adjustment is actually done. Check results with a tuning wand (see page 6).

4. Set oscillator to 18 metres (16-66 Mc.), tune-in on receiver and adjust TCI for maximum output whilst "rocking" the gang condenser.

5. Repeat operations 1, 2, and 4, checking results with a tuning wand.

MEDIUM AND LONG WAYES.

Set receiver to MW and other controls as for SW

ganging :

1. Tune oscillator to 195 metres (1,538-5 kc.) set gang condenser to minimum and adjust TC9 for maximum output.

2. Set receiver to 225 metres (1,333.3 kc.) by scale and tune oscillator to this frequency. Adjust TC2 and

TC4 for maximum output.

3. Set oscillator to 530 metres (566 kc.) tune-in signal on receiver and adjust TC10 for maximum output, at the same time "rocking" gang condenser.

4. Repeat operation 1, checking all circuits with a

tuning wand.

5. Turn wavechange switch to LW and set gang condenser to minimum. Tune oscillator to 725 metres (413.8 kc.) and adjust TCII for maximum output.

6. Set oscillator and receiver (by scale) to 800 metres (375 kc.) and adjust TC3 and TC5 for maximum output.

7. Set oscillator to 1,900 metres (157-9 kc.) tune-in on receiver and adjust TC12 for maximum output at the same time "rocking" the gang condenser.

8. Repeat operation 5, and check all circuits with a

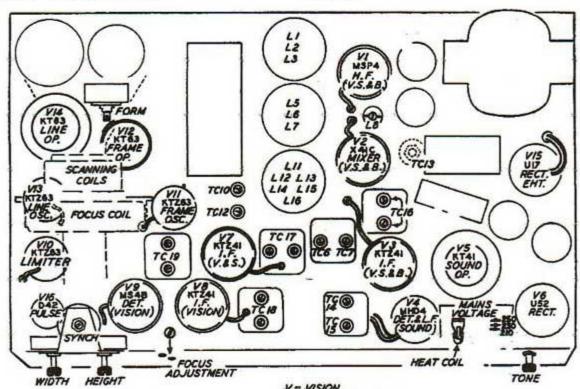

tuning wand.

NOTE .- The tuning wand is used to check circuits as follows :-

(a) Insert ferrocart end of the wand into the can containing the coll of the circuit being aligned. If output reading falls, leave trimmer set, and if reading increases, increase capacity of trimmer until peak reading is obtained.

(b) insert brass end of wand, and if reading falls leave trimmer set, but if output reading increases decrease trimmer capacity until a peak reading is

obtained.

V = VISION S = TELEVISION SOUND B = BROADCAST SOUND

TELEVISION

For measurement of output of the vision signal, a D.C. milliammeter must be connected in the anode circuit (top cap lead) of V9. The sound signal is measured on the output meter as for broadcast sound. It is advisable to switch on the receiver and oscillator if mains driven at least 15 minutes before commencing aligning operations to allow a condition of stability to be reached.

I.F. ALIGNMENT.

Connect output leads of oscillator to grid (top cap) V2 (X4IC) and chassis, set waveband switch to TEL, and turn Contrast control fully clockwise.

- Tune oscillator to 4.5 Mc. (66.67 metres) and adjust TC18, for maximum output on sound output meter.
- Adjust TCI7 and TCI6 for maximum output on sound output meter.
- Adjust TCI9 for minimum output on milliammeter (vision output meter).
- Set oscillator to 8 Mc. (37.5 metres) and tune
 L28 for maximum vision output (milliammeter).
- Set oscillator to 8.7 Mc. (34.48 metres) and tune L24 for maximum vision output.
- Set oscillator to 7-3 Mc. (41-1 metres) and tune L22 for maximum vision output.
- 7. Set oscillator to 8.0 Mc. and tune L18 for maximum vision output.
- Leave oscillator set and tune L28 for maximum reading.
- Alter oscillator to 4.5 Mc. and adjust TC19 for minimum reading on the vision milliammeter.
- Adjust TC18 for maximum reading on sound output meter.
- 11. Set oscillator to 8.7 Mc, and tune L24 for maximum vision output.
- Set oscillator to 4.5 Mc. and adjust TC17 for maximum sound output.
- Set oscillator to 7-3 Mc. and tune L22 for maximum vision output.
- Set oscillator to 4.5 Mc. and adjust TC16 for maximum sound output.
- 15. Set oscillator to 8-0 Mc. and adjust L18 for maximum vision output.
- 16. Check the band width of the vision I.F. circuits as follows:—
 - (a) Switch off oscillator and note reading of milliammeter.

- (b) Switch on oscillator, tune to 8 Mc. and adjust oscillator attenuator to give a milliammeter reading 3.0 mA more than (d) and note value.
- (c) Increase oscillator attenuator to exactly twice the input (microvolts) and reset oscillator to 8.5~Mc, and then 7.5~Mc.

Note that the milliammeter readings are not less than that noted in (b).

If this condition cannot be fulfilled the entire television I.F. ganging should be checked working always in the order given above.

R.F. GANGING.

Connect oscillator to the television aerial and earth sockets. Output meters to be connected as detailed under "I.F. Alignment." Turn Contrast control to maximum.

- i. Tune oscillator to 41.5 Mc. (7.23 metres) and trim TC13 for maximum sound output.
- 2. Tune oscillator to 45 Mc. (6.67 metres) and adjust L4 and L9 for maximum vision output. If L8 is done from the underside of the chassis an entirely non-metallic screwdriver must be used.

IMPORTANT.—Check the setting of TCI3 and sound/vision ratio on an actual television transmission, see page 5.

GANGING ON TELEVISION SIGNALS.

Apart from the adjustment of the oscillator circuit (TCl3) on television transmission it is very easy, and even desirable, to do the entire R.F. ganging by this means. It must be clearly understood, however, that it is not possible to do the I.F. ganging on a television transmission, and it should on no account be attempted.

Observation of output in the case of vision may be made by means of the milliammeter suggested above, but it is perhaps preferable to use the actual picture on the tube for this purpose. In the case of sound output, the A.C. voltmeter, or output meter, cannot be used, but there is no objection to judging this aurally if done carefully.

Follow the procedure given for "oscillator" ganging, treating the incoming signal as an oscillator input of 41.5 Mc. and 45 Mc. and using the "Contrast" control as an attenuator.

The best way to "measure output" by the picture is to reduce the Contrast control until the synch. just breaks (be sure the Frame and Line Hold controls are correctly set) and make the trimming adjustments with the object of re-establishing "hold."

VALVE TABLE

Values ± 15 per cent. Voltages measured on meter having a resistance of approx. 1,000 ohms per volt.

The following values were taken on a model operating on 220 volt mains (230 volt tapping).

All resistance readings taken with the wave-change switch in the TEL position, values approximate.

Absence of a voltage reading does not necessarily mean that no voltage will be found, but merely that the value is regarded as of little interest.

* In these cases the connexion of a meter to the test point either entirely upset the operation of the receiver (where no value is given) or affected it in some way. For instance, the anode values on V2 and V7 had to be taken on the H.T. side of the anode impedance, whilst the connexion of a meter to the anodes of VII and V3 affected the amplitude or frequency of the frame or line oscillators. SLOTTED FIXING FOR PICTURE STRAIGHTENING

FAULT TABLE

Symptom.	Probable Cause.	Analysis.
Picture unsteady	Synch. pulses not reaching time bases	Check VI6, VI0, and setting VRII (synch. control).
Picture lacking contrast	Insufficient input, or gain	Check aerial, VI, V3, V7, V8. Contact aerial between top cap VI and chassis and then V2 and chassis. If results do not progressively deteriorate suspect VI.
Picture low brightness	Low E.H.T. volts or incorrect bias. Low H.T. volts	Check VI5, check voltage at C.R. tube grid (see valve table). Check H.T. voltage and V6, or change C.R. tube.
Picture too bright	Cathode D.C. voltage low	Check V9 emission.
Picture with pattern on	Diathermy interference, or spurious oscilla- tion	For latter, examine all screening or re-gang, check decoupling condensers for open circuit.
Poor definition	Focus out of adjustment or I.Fs. out of alignment Mains voltage adjustment incorrectly set.	If it is possible to get sharp clear lines on a plain raster (aerial disconnected), I.F. ganging must be done. Also see note under circuit diagram, p. 11.
Horizontal line	No frame deflection	Check VII, VI2, L30, L31.
Verticafline	No line deflection	Check VI3, VI4, L33, L34.
Small light spot in centre of tube	No frame or line deflection	Check all items in two lines above.
Large diffuse spot in centre of tube	No focus, faulty H.T. rectifier	Check L32, V6.
Large dark spot in centre of tube	Ionic bombardment	Change C.R. tube.
Insufficient width or height	Faulty line or frame output valves	Check VI2 and VI4 cathode voltages or change valves.
Interference crackles and splashes of half of picture, similar to car inte ference		Turn down volume, and the arcing in the base should be audible and/or visible if present. Change valve.
Poor line definition	Incorrect focusing field, or soft C.R. tubo	Try changing R57 (see note on p. 11). Examination of the tube "gun" will reveal faint blue glow if the tube is soft.
Sound on picture	Incorrect adjustment of TCI6 or sound	Check these adjustments referring to H.F. Tests and Adjustments.
Synch. on sound	Faulty decoupling of H.T. feed, faulty V9, 10, or 16. Screened lead passing through field of T5.	Check CKI and condensers: if "contrast" has to be turned right up, try changing V9, I0, or II. Move lead.
"Ringing" or images	Incorrect aerial feeder impedance, faulty I.F. alignment (I.F. stages verging on instability), or "reflections" reaching aerial	The difference between "ringing" and an image may be established by turning up the "Contrast" control. Rings increase in number as the control is turned up, whereas a true image is unaffected; it is usually more distant from the true picture that "rings." See E.M.I Service "Aerial Brochure."
No television or radio	X4Ic not oscillating	If valve is oscillating a marked increase in voltage should be noted. Repeat with Ri

ATTENUATION

Attenuators comprising a network of resistances, so designed that the impedance and frequency characteristics of the cable are unaffected, are obtainable from E.M.I. Sales & Service Ltd.
