SPECIFICATION

PHYSICAL.

	Model 907
Height...	39½ inches
Width ...	17½ inches
Depth ...	22½ inches

Net weight—both models—136 lb.
Gross weight—both models—145 lb.

VOLTAGE RANGE.

200 to 250 volts, 50 cycles.

At 224 volts—	98 volt amps	Radio.
	85 watts	
	248 volt amps	Television
	230 watts	

FUSES.

This model is fitted with a Heat Coil.

Part No. 16705B. Yellow. 1·6 amp.

Nevertheless, it is recommended that it should not be connected to a supply point fused to carry more than 5 amperes.

SPEECH OUTPUT.

Approximately 3 watts maximum.

WAVELENGTH RANGE.

Television, fixed tuned	6·67 metres, Vision.
	7·23 metres, Sound.
Broadcast	13·5 — 50 metres, Short Waves.
	195 — 580 metres, Medium Waves.
	950 — 2,000 metres, Long Waves.

Model	709
Height	39 inches
Width	18 inches
Depth	23 inches

VALVES.

Marconi	MSP4	H.F. Amplifier, television (V1).
"	X41C	Frequency Changer, television (V2).
"	X65	Frequency Changer, broadcast (V11).
"	KTZ4I	I.F. Amplifier, television and broadcast (V12).
"	MHD4	(Met.) Sound Detector and A.V.C. (V13).
"	KT4I	Sound output (V14).
"	KTZ4I	I.F. Amplifier, television only (V3).
"	KTZ4I	I.F. Amplifier, vision only (V4).
"	D42	Vision Detector (V5).
"	KTZ4I	Vision Frequency Amplifier (V6)
"	D42	Pulse Diode (V7).
"	MSP4	Limiter (V8).
"	MS4B	Frame Oscillator (V9).
"	MKT4	Frame Output (V10).
"	MS4B	Line Oscillator (V15).
"	KT4I	Line Output (V16).
"	U16	Extra H.T. Rectifier (V18).
"	U52	H.T. Rectifier (V17).

Emiscope Tube type 3/3.

Pilot Lamps 3—6·3v 0·3 A

Part No. 22704 H

LOUDSPEAKER.

No. 20277D.

An electro-magnet loudspeaker is employed on these Models.

D.C. resistance of speech coil, 4 ohms.

Impedance at 800 cycles, 5 ohms.

D.C. resistance of field, 1,600 ohms.

An extra loudspeaker may be connected to the sockets provided. The extra loudspeakers should be adjusted to a total impedance of approximately 5 ohms.

The internal loudspeaker may be silenced by removing the yellow plug from the third socket on the E.L.S. panel.

CONNECTING A PICK-UP.

A high resistance pick-up may be permanently connected to the sockets provided. The leads should be connected to the top sockets and the lead screening to the bottom socket.

CIRCUIT DESCRIPTION

Owing to the multiple functions of certain of the stages in this receiver a transparent sheet showing the general paths of the various signals is fitted over the circuit. From this it will be seen that there is an H.F. stage for television only (V1), two frequency changers, one for television and one for broadcast (V2 and, V11) and three I.F. stages. The first I.F. stage handles television and broadcast; the second, television (sound and vision); and the third, vision only. After the diode vision detector is a V.F. amplifier.

BROADCAST RECEIVER.

A single pre-selection tuned circuit using efficient inductances is employed for each waveband between the aerial and the grid of the frequency changer. The coupling circuit is designed to maintain efficient coupling on all wavebands and to give image rejection. The triode-hexode frequency changer has tapped circuits L9 and L10 employing mixed capacitive and inductive coupling for the production of oscillations on M.W. and L.W. On S.W. coupled coils L8, L11 are

employed. An I.F. transformer (L12, L13) couples the frequency changer to V12.

The tetrode V12 (KTZ4I) is an I.F. amplifier, which has A.V.C. bias on S.W., M.W. and L.W., and is coupled by a second I.F. transformer to the second detector.

The double diode triode second detector for sound (V13) has a load resistance R22 and also supplies A.V.C. voltage (diode fed from anode V12 via C44). It is resistance capacity coupled to the sound output valve V14.

TELEVISION RECEIVER.

The H.F. amplifier V1 (MSP4) is preceded by a single broadly tuned coil, and coupled by a broadly tuned transformer (L20, L21) both accepting the vision and sound signals, to the frequency changer.

A high stability triode-hexode (X41C) with a Hartley type oscillator circuit (L22) is chosen and this is coupled by a bi-resonant circuit (L61 and L34, TC12) to the I.F. amplifier.

The couplings between the I.F. stages have sound circuits (L34, L17) and vision circuits (L16, L25, L27). The voltage from the last sound circuit is taken from a coupling coil L18 and applied to the diode of V13 for sound detection, L26 is a sound rejector circuit, whilst L28 is a series choke feeding the V.F. amplifier grid. On television, there is no A.V.C. but gain is controlled by VR1 which varies the bias of the first three stages ; this is the "contrast" control.

VISION DETECTOR AND SEPARATION.

A diode (V5) is used as vision detector ; the load resistance is R38. The rectified signal is passed via L28 to the V.F. amplifier (V6), which is negatively biased from the potentiometer VR4. The anode of V6 feeds the modulating electrode of the C.R. tube (the cathode) via R43, C53 and L29.

Separation of the sync. pulses from the modulation is done by V7 and V8. The anode load for V6 is in two parts, R42 and R41, and the action of the pulse diode is virtually to short circuit R41 during the picture portion of the signal. During the sync. pulses, however, a voltage is applied through C55 to the grid of the limiter V8, which keeps the pulses within certain limits and passes them on to "trigger" the line and frame oscillators via C84 and C60 respectively.

TIME BASES.

Hard valves operating on the "blocking" oscillator principle are used for both frame and line time bases.

H.F. TESTS AND ADJUSTMENTS

INSTALLATION ADJUSTMENTS.

Further to the information on the service sheet an abridged instruction for installation is given below.

Aerial and Cable.

A properly designed aerial with a lead-in of correct impedance (such as those obtainable from E.M.I. Service, Ltd.) must be used to ensure good reception.

The Tuning of Receiver and Adjustment of Aerial Input.

1. Loosen securing nut TC5 and adjust for maximum sound, keeping volume control at maximum and "contrast" control to give low volume. Re-secure clamping nut.
2. If when "contrast" is turned almost to maximum hardly sufficient signal is received, the tuning should be checked (see (1) above), or aerial height and position checked or a different lead-in used. If when "contrast" is set to minimum a steady picture is obtained there is too much signal and either a different lead-in of lower loss must be employed or an aerial attenuator fitted.

Sound/Vision Ratio.

If the sound signal is too high when the picture is

These circuits have the usual reaction transformers (T3 and T2) and grid leak and condenser (R53, VR9, C62 and R52, VR8, C61).

Negative feed-back is employed in both frame and line output stages, and the usual wave-form circuit is connected across the secondary of the line frequency output transformer, whilst the frame coils are resistance capacity coupled. The amplitude of the frame and line oscillations are controlled by varying the anode voltage by means of VR6 ("height") and VR5 ("width").

THE C.R. TUBE.

The modulator (cathode) has already been described, and the other two electrodes (the tube is a triode) are the "grid" and the anode. A D.C. voltage derived from a potentiometer, including VR5, VR6, etc., and VR7 across the H.T. feed is applied to the grid as bias ; variation of this voltage (by VR7) consequently varies brightness. The anode operates at approximately 3,500 volts, fed from a half-wave rectifier (V18) with the usual resistance capacity smoothing (R70, R86, C71, C72) and voltage stabilizing drain resistances R65—R69. The focusing of the beam is done magnetically by means of a coil (L35) round the neck of the tube. This coil is enclosed in an iron yoke, and adjustment of the current through the coil is done by VR11 (Focus control) and the pre-set adjustment VR13.

normal the trimmer TC13 should be screwed in until modulation bars across the picture caused by high sound signal are no longer apparent.

Synchronisation Adjustment.

When it is difficult to make the picture hold such as when the field strength is rather weak, it may be necessary to turn the sync. control (located just behind the aerial panel) in a clockwise direction. The sync. control must not be turned so far that an intensification of the picture contrast is noticed.

If the sync. control will not give proper synchronisation, check the setting of VR4 which should be set to exactly —2.5 volts between the moving arm and chassis.

GANGING.

The broadcast side of this receiver may be treated as an ordinary sound radio insofar as alignment of circuits is concerned. In the event of it being necessary to re-align the I.F. circuits complete R.F. alignment must follow, but if only an R.F. circuit has been disturbed the R.F. alignment for that waveband only should be all that is required.

On television, if possible, even greater care must be exercised than on broadcast, otherwise picture quality will suffer. Generally speaking, low sensitivity or unsatisfactory picture/sound ratio is the result of mistuning of the R.F. circuits, whilst lack of definition in the picture is due to faulty I.F. alignment. As in broadcast, if the I.F. circuits are touched, the R.F. circuits must be done.

Apparatus required for broadcast ganging.

- (a) A modulated oscillator or signal generator with attenuator tuning from 16 to 1,900 metres (18.75 Mc. to 157 kc.).
- (b) An output meter or 0-2 A.C. voltmeter.
- (c) A trimming screwdriver with minimum of metal in the blade, a tool for adjusting coil loops, a special trimming tool (Stock No. Q2527) and a tuning wand. In addition to the above for television ganging the oscillator must tune down to 6.67 metres (45 Mc.), and an 0-10 or 12 D.C. milliammeter will be required.

Broadcast Receiver.

The A.C. voltmeter should be connected across the extra loudspeaker sockets or the anode of the sound output valve V14 (KT41) and chassis if the E.M.I. Service output meter is used. During all ganging operations the input to the receiver from the oscillator should be kept low and progressively reduced as the circuits are brought into line, in order that the reading on the output meter does not exceed 500 M.V. or 1.3 volts.

I.F. Alignment.

Set the receiver to L.W., tone control to maximum top, gang condenser to maximum and volume control to maximum. The oscillator must be connected via a 0.1 mfd. condenser to the top cap of VII (X65), leaving grid connection made.

1. Tune oscillator exactly 465 kc. (645.2 metres).
2. Adjust TC3, TC4, TC8 and TC9 in that order for maximum output.
3. Re-check operation 2 in the same order.

Short Waves.

IMPORTANT.—It is essential that, before ganging, the position of the pointer in relation to the wave-scale is checked. A small mark will be found at the bottom right-hand corner of the scale, just below the L.W. calibration. With the gang condenser fully in, the pointer should coincide exactly with this mark. All ganging is now done to settings on the scale itself, and the gang condenser must not be rocked, or the positioning of the pointer altered in any way. The use of this method will produce accurate calibration. Switch the receiver to S.W., set volume control to maximum, tone control to maximum top and connect

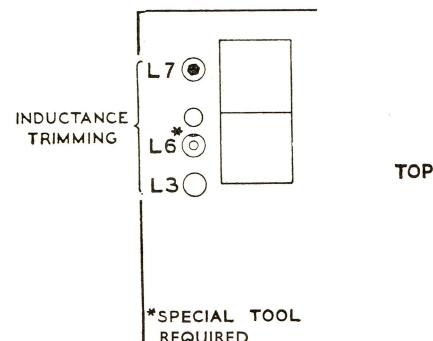

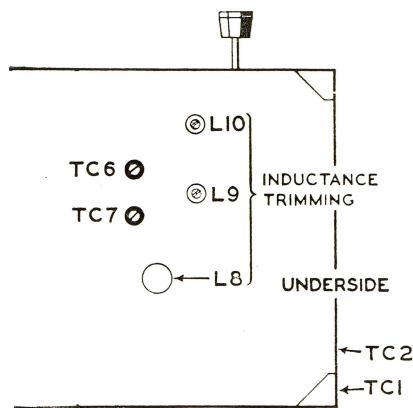

oscillator to aerial and earth sockets via a suitable dummy aerial.

1. Set oscillator and receiver (by the tuning scale) to 30 metres (10 Mc.) and adjust the loops L8 and L3 for maximum output. These loops will be found inside the coil formers and may be adjusted with a strip of insulating material with a nick in it by bending the loop either towards or away from the chassis. The coil L3 can be adjusted through a hole in the top of the chassis. Check results with a tuning wand.

Medium and Long Waves.

Set the receiver to M.W. and other controls as for S.W. ganging.

1. Set receiver to 225 metres (1,333.3 kc.) by scale and tune oscillator to this frequency. Adjust TC7 for maximum output.
2. Set receiver to 530 metres (566 kc.) by the scale and tune oscillator to the same frequency. Now adjust the plunger of L9 for maximum output.
3. Repeat operations 1 and 2.
4. Repeat operation 1.
5. Set receiver (by scale) to 225 metres, tune oscillator to this frequency and adjust TC2 for maximum output.

6. Tune receiver and oscillator to 530 metres and adjust core of L6 for maximum output by means of the special tool (Stock No. Q2527). It should be inserted through the hole in the chassis, the point located in the hold in the paxolin coil mounting strip and the rubber bush bearing on the core. The core may now be rotated by turning the tool.

7. Repeat operation 5.

8. Set receiver to L.W.

9. Set receiver to 1,100 metres (272.7 kc.) by the tuning scale and adjust the oscillator to the same frequency. Now adjust TC6 for maximum output.

10. Set receiver to 1,900 metres (158 kc.) by the scale and tune oscillator to the same frequency. Now adjust the plunger of L10 for maximum output.

11. Repeat operation 8.

12. Return to 1,100 metres and adjust TCI for maximum output.

13. Tune oscillator and receiver to 1,900 metres and adjust core of L7 for maximum output.

14. Tune oscillator to 1,400 metres and set receiver to this wavelength. Re-adjust TCI for maximum output.

NOTE.—Check circuits with tuning wand as follows :—

(a) Insert ferrocarr end of the wand into the coil of the circuit being aligned. If output reading falls, leave trimmer set and if reading increases, increase capacity of trimmer until peak reading is obtained.

(b) Insert brass end of wand and if reading falls leave trimmer set, but if output increases, decrease trimmer capacity until peak reading is obtained.

TELEVISION

For measurement of output a D.C. milliammeter reading 0-12 should be connected in the anode circuit of V6 across R41. This is effectively a short circuit for R41, but at the same time gives measurement of anode current of V6 (KTZ41). The sound signal is measured on the output meter as for broadcast sound. It is advisable to switch on the receiver and oscillator, if mains driven, at least fifteen minutes before commencing the aligning operations, to allow a condition of stability to be reached.

TELEVISION SOUND I.F. ALIGNMENT.

1. Disconnect grid lead from V2 and connect the oscillator output leads between grid (top cap) of the valve and chassis. Connection to the grid should be via a 0.1 mfd. condenser and a 1,000 ohm resistance should be connected between the grid and chassis. Short out the television oscillator coil L22, which is reached through a hole in the screen.

2. Set volume control to maximum, tone control to maximum top, and contrast control to maximum, and inject modulated signal of 4.5 Mc. (66.67 metres).

3. Adjust TC11, TC12 and TC13 for maximum output on sound output meter.

4. Repeat operation 3 in the same order.

SOUND REJECTOR CIRCUIT.

1. Connect oscillator between grid V3 and chassis and inject a strong signal of 4.5 Mc. (66.67 metres).

2. Adjust TC10 for minimum output on V6 anode milliammeter.

TELEVISION VISION I.F. ALIGNMENT.

1. Connect oscillator and output metres as detailed above.

2. Set oscillator to 7 Mc. (42.86 metres), the signal need not be modulated, and tune the plunger of L27 for maximum output on vision output meter.

3. Set oscillator to 9.25 Mc. (32.43 metres) and tune the plunger of L25 for maximum output on vision meter.

4. Set oscillator to 7 Mc. (42.86 metres) and tune the plunger of L16 for maximum output on the vision meter.

5. Set oscillator to 8.7 Mc. (34.48 metres) and tune

the plunger of L24 for maximum output on the vision output meter.

Do final trimming to Television sound and vision circuits in the order TC13, L24, TC12, L16, TC11 and L25, as detailed below.

TELEVISION I.F. BANDWIDTH.

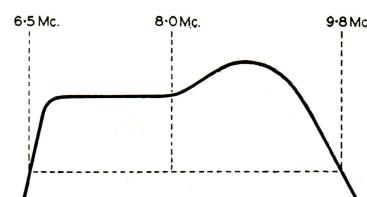

1. With oscillator and output meters connected as for I.F. vision alignment, contrast at maximum, inject a signal at 8 Mc. and adjust oscillator attenuator to give approximately 5 mA on vision output meter.

2. Increase input from oscillator by 10 times, and reduce "Contrast" control to regain original output reading obtained in (1).

3. Double input voltage by again turning up attenuator, and re-tune oscillator to 6.5 Mc. and 9.8 Mc.

4. The reading on the output milliammeter at these frequencies should not be less than that obtained in operation 1.

5. Sweep the oscillator over the band 6.5 to 9.8 Mc. and note vision output meter. The readings should express a response curve of the form shown below.

TELEVISION R.F. GANING.

Connect oscillator to aerial and earth sockets. Turn contrast to maximum. Connect up output meters as detailed under "I.F. Alignment."

1. Tune oscillator to 45 Mc. (6.667 metres) and tune plungers of L19, L20/L21 for maximum output.

2. Note reading on vision output meter, and increase input from oscillator by ten times.

3. Now reduce contrast control to regain original output reading and re-adjust L20/L21 for maximum output.

4. Re-adjust oscillator trimmer (TC5) on transmission and sound/vision ratio if necessary, see page 3.

GANDING ON TELEVISION SIGNALS.

Apart from the adjustments of the oscillator circuit TC5 which should always be done on Television transmission, it is very easy and even desirable to do the entire R.F. ganging by this means. It must be clearly understood, however, that it is not possible to use this method for I.F. ganging and it should on no account be attempted.

Observation of output in the case of vision cannot be made with the milliammeter detailed above, but in any case, it is preferable to use the actual picture on

the tube for this purpose. In the case of sound output it is not possible to use the A.C. voltmeter or output meter but there is no objection to judging this aurally if care is taken.

Follow the procedure given for "oscillator" ganging, treating the signal as an oscillator input of 41.5 Mc. and 45 Mc. and using "Contrast" control as an attenuator.

The best way to "measure output" by the picture is to reduce the "Contrast" controls until the sync. just breaks. (Be sure "Frame" and "Line" hold controls are correctly set) and make the trimming adjustments with the object of re-establishing "hold."

Values \pm 15 per cent.

CONTINUITY CHECKS

Component.	Measured.	Switch.	Resistance.

VALVE TABLE

Values \pm 15 per cent.

Voltages measured on meter having a resistance of approx. 1,000 ohms per volt.

The following values were taken on a model operating on 220 volt mains (211-230 volt tapping).

All resistance readings taken with the wave-change switch in the TEL position, values approximate.

Absence of a voltage reading does not necessarily mean that no voltage will be found but merely that the value is regarded as of little interest.

NOTE COMPONENT NUMBERS ARE MARKED IN *ITALICS*

NOTE COMPONENT NUMBERS ARE MARKED IN *ITALICS*

FAULT TABLE

Symptom.	Probable Cause.	Analysis.
Picture unsteady	Synch. pulses not reaching time bases ...	Check V7, V8, and setting VR4 (synch. control).
Picture lacking contrast...	Insufficient input, or gain	Check aerial, V1, V2, V12, V3, V4, V5, V6. Contact aerial between top cap V1 (via a small condenser) and chassis and then V2 and chassis. If results do not progressively deteriorate suspect V1.
Picture low brightness	Low E.H.T. volts or incorrect bias. Low H.T. volts	Check V18, check voltage at C.R. tube grid (see valve table). Check H.T. voltage and V17 or change C.R. tube.
Picture too bright	Cathode D.C. voltage low	Check C53.
Picture with pattern on	Diathermy interference, or spurious oscillation	For latter, examine all screening or re-gang, or check decoupling condensers for open circuit.
Poor definition	Focus out of adjustment or I.F.s. out of alignment. Mains voltage adjustment incorrectly set.	If it is possible to get sharp clear lines on a plain raster (aerial disconnected), I.F. ganging must be done.
Horizontal line	No frame deflection	Check V9, V10, L30, L31.
Vertical line	No line deflection	Check V15, V16, L32, L33.
Small light spot in centre of tube ...	No frame or line deflection	Check all items in two lines above.
Large diffuse spot in centre of tube ...	No focus, faulty H.T. rectifier	Check L35, V17.
Large dark spot in centre of tube ...	Ionic bombardment	Change C.R. tube.
Insufficient width or height ...	Faulty line or frame output valves	Check V10 and V16 cathode voltages or change valves.
Interference crackles and splashes on half of picture, similar to car interference	Faulty insulation in pinch of V10 or V16 ...	Turn down volume, and the arcing in the base should be audible and/or visible if present. Change valve.
Car Interference causing synchronising to break	D.C. level not correctly maintained	Fit 50 mfd. 12v. condenser (Part No. 17250 F) across C49. Connect the positive side of the condenser to chassis.
Poor line definition	Incorrect focussing field, or soft C.R. tube ...	Examination of the tube "gun" will reveal faint blue glow if the tube is soft.
Sound on picture	Incorrect adjustment of TCI3 or sound rejector circuit (TCI0)	Check these adjustments referring to H.F. Tests and Adjustments.
Sync. on sound	Faulty decoupling of H.T. feed, faulty V5, 6, 7 or 8	Check CK1 and condensers ; if "contrast" has to be turned right up, try changing V5, 6, or 7.
" Ringing " or images	Incorrect aerial feeder impedance, faulty I.F. alignment (I.F. stages verging on instability), or " reflections " reaching aerial	The difference between "ringing" and an image may be established by turning up the "Contrast" control. Rings increase in number as the control is turned up, whereas a true image is unaffected ; it is usually more distant from the true picture than "rings." See E.M.I. Service "Aerial Brochure."
No television or radio	X41c or X65 not oscillating	Connect voltmeter across R14, and short L22. If valve is oscillating a marked increase in voltage should be noted. Repeat with R8 and short VC2 for broadcast check.

Attenuators comprising a network of resistances, so designed that the impedance and frequency characteristics of the cable are unaffected are obtainable from E.M.I. Service Ltd.
